# MOTOR LEARNING 72 IN PRACTICE Skill Acquisition

By the end of the course, students will:

- Describe the stages of motor learning (e.g., cognitive, associative, autonomous) and the role of feedback and transferability in skill acquisition.
- Describe the physical and psychological factors that affect skill performance (e.g., fatigue, visualization, motivation, audience).

### After completing this chapter you should be able to:

- O explain the skill acquisition process and describe the stages of learning a skill;
- O describe the types of feedback and their roles in skill learning;
- O identify the types of transfer and apply transfer principles to learning a skill;
- O design a learning environment using effective practice methods.

For a summary of key terms, see TGS 12.1.

After reviewing the five main factors affecting skill acquisition, ask students to consider how one or more of these factors have had an impact on their motor development.

Distinct changes that occur as a skill is learned and developed are easy to detect because the execution becomes swifter and more fluid and demands much less attention. Your own experiences provide an example of how motor skills change and develop. Your first steps may not have been perfectly executed, but look at you now, walking with the best of them. Certainly, your early attempts at playing the piano, serving a tennis ball, or shooting a basketball were not worthy of acclaim; but with practice and proper guidance, major improvements undoubtedly followed.

# **Conditions for Skill Acquisition**

Every artist was first an amateur. RALPH WALDO EMERSON Before individuals can become skilled in any activity, they must first acquire a basic movement repertoire consisting of certain fundamental movement skills. The important questions to ask here concern the best time and conditions under which movement intelligence (discussed in Chapter 11) may be acquired. Research and practice have identified several factors that affect the development of an individual's movement intelligence: starting at a young age, providing sufficient learning time, being taught by qualified instructors, following the right progression, and using quality equipment. These factors are discussed in more detail in this section.

# **Starting at a Young Age**

The importance of beginning the learning process at a young age was discussed in Chapter 10. Education involving movement skills should begin early, even as early as the preschool years. Developing fundamental skills such as walking, throwing, catching, and climbing early on allows a child to incorporate these skills (which are the basis for numerous other activities) effectively into a repertoire of motor skills. Because movement patterns are still being established in young children, it is important to teach skills correctly the first time to avoid the development of bad habits early.

Getting started early and providing sufficient learning time are vital in developing movement intelligence.

254 Foundations of Kinesiology

# **Learning Is Fundamental**

Divide students into small groups and have them discuss which fundamental movement activities or sports all young children should be taught in order to maximize their success in a variety of sports later on. Students should comment on how these specific activities serve to develop specific fundamental skills. The groups can then share their ideas with the class.

### **Providing Sufficient Learning Time**

A large amount of time during the school day is traditionally dedicated to the acquisition of the more important cognitive skills (e.g., linguistic and mathematical). Similarly, in order to improve an individual's motor skill development, sufficient time must be allotted to participating in physical activities that enhance movement skills. Without physical experience, skills cannot be learned effectively and maintained.

### Being Taught by Qualified Instructors

Instructors, physical educators, and coaches must be properly trained and have experience with teaching physical activity in order to teach movement skills. But too commonly, unqualified staff are given the task in schools, community programs, and sports camps. Students deserve the best level of instruction available.

### **Following the Right Progression**

Choosing the right progression to follow has a direct influence on the acquisition of movement skills. In other words, the organized action and the sequence of drills ensure that skills are easier to grasp. For example, you might introduce children to baseball by playing tee-ball (which simplifies the game) and slowly incorporating a live pitcher for batting (slow-pitch first). The skills learned from simpler tasks can then be effectively transferred to more complex tasks.

### **Using Quality Equipment**

The quality of equipment available for teaching movement skills is also important for effective learning. Safe, appropriate, and well-maintained equipment makes learning most effective for students. And since children have different needs from teenagers or adults, equipment that is scaled down to their size (e.g., lower basketball hoops, smaller basketball and soccer balls, smaller soccer nets, lighter baseball bats, and so on) is essential.

Many other factors have an impact on the teaching and acquisition of motor skills. This chapter will review a number of related topics to provide a broad-based perspective on the skill acquisition process.

Scaled-down equipment for children is a must for proper skill learning. Imagine how you would feel in an environment where everything was twice its normal size.

Studying 🖉

Discussion Guiding Question

 List the five major factors that influence the acquisition of movement intelligence.

> Starting at a young age Providing sufficient learning time Being taught by qualified instructors Following the right progression Using quality equipment

### **Talent Takes Time**

Mastering a skill takes time. Conduct a poll of the class to see how many of the students play a sport or an instrument. Find out how many hours a week they practise, on average.

1+h 255

### Well Equipped

МІГ.Н

Mover

The lack of quality equipment for young students and athletes can be a significant obstacle to overcome. How can a beginning oarsman be expected to learn the proper rowing strokes using warped rowing blades in an old, worn, and warped rowing boat? Engage the entire class in a discussion about the importance of quality equipment and how the school has fared in providing the necessary conditions for optimal motor development (e.g., proper equipment, adequate gym time, adequate facilities, trained instructors, balanced budgets).

# Stages of Learning a Skill

How?

Knowledge advances by steps, and not by leaps.

When?

What?

Research and practice have identified three general stages that individuals must go through as they learn and develop motor skills. These three stages (cognitive, associative, and autonomous) are summarized in Table 12.1 and are discussed in more detail in this section. We will outline the changes that occur as motor learning takes place and the important features that are unique to each stage.

### **Cognitive Stage**

The cognitive (understanding) stage begins when the task is first introduced to the learner. As the skill is completely new, the first major goal for the

learner is to determine cognitively the general shape of the particular skill and the goals to be achieved. Questions concerning what, when, and how predominate at this early stage as the learner tries to get a feel for the activity.

Instruction, demonstrations, films, videos, and vivid descriptions serve to convey the general idea of the skill to the learner. Some learners even verbally guide themselves through skills by engaging

in self-talk. Giving themselves some verbal reminders as they attempt a skill for the first time offers security and begins to instill the major ideas associated with performing the skill.

# Terminology A!ert

instructions are verbally transmitted to the learner, the cognitive stage is sometimes referred to as the **verbal stage**.

For example, a beginner in gymnastics may remind herself to tuck her head on the forward roll or to stay balanced on the beam. However, this strategy demands concentration and does not allow other information to be processed simultaneously. But during this initial stage, verbal activity can give the learner a rough idea of what the skill is all about and even facilitate rapid learning and considerable improvement.

Although performance at this stage may be slow, jerky, highly variable, and even awkward at times, it serves as a good foundation on which to build.

### **Associative Stage**

With some practice, the learner can move to the associative (practice) stage of learning. This second stage is focused on performing and refining the skill by organizing more appropriate movement patterns. Now that most of the stimuli related to the skill have been identified and defined, a greater amount of concentration can be directed to refining details.

For example, the learner can experiment with how timing can be improved by using environmental cues, as well as how movements can become more efficient and executed with increased speed. Practice allows the learner to make certain movements more automatic and controlled. The motor programs introduced in Chapter 11 can begin to develop and make skilled movements more fluid and consistent. Variability of performance from one attempt to another also begins to decrease. As performers discover what constitutes an effective performance, their confidence increases.

256 Foundations of Kinesiology

Differentiated Instruction

### As Easy as 1, 2, 3?

Have students learn how to juggle three balls (or something lighter like scarves) to help illustrate the key concepts behind the cognitive, associative, and autonomous stages of learning. How much of their efforts go toward thinking about what each hand is doing during the cognitive stage? Are they able to focus on other stimuli around them as they progress to the associative and autonomous stages? Students should consider how athletes operating in the autonomous stage benefit from executing skills with a high degree of success without much thought.

 Identify the three stages of learning a motor skill.

> Cognitive (understanding) stage Associative (practice) stage Autonomous (application) stage

Learners do not make abrupt shifts from one stage to the next. In most learning environments there is a gradual transition or change in the learner's performance characteristics from stage to stage, which makes it difficult to detect which stage a learner is in at any given moment. Table 12.1 Three-stage model for learning a motor skill. **Cognitive Stage Associative Stage** Autonomous Stage Focus on smaller details leads to skill Skill execution is automatic, allowing Learners get the general idea or overall concept of the skill focus on other aspects of performance refinement Performance may be slow, jerky, and Performance is more fluid, controlled, Performance is effortless, relaxed, and highly variable with many errors and consistent with fewer errors accurate with few errors Early practice involves demonstrations Practice helps maintain skills with less and vivid descriptions with lots of Lots of practice takes place over long dependency on instruction and more verbal input from instructors and selfperiods of time with expert instruction self-monitoring talk by learners Performance improvements are Performance serves as a foundation on Rapid performance improvements relatively slow with less room for which a learner can build occur with vast potential for growth improvement Understand, Practice Apply

Motor Learning in Practice

An increased ability to self-correct and make minor adjustments to the execution of a skill

an Movement and Health 🚦 257

is one of the hallmarks of an individual in the

autonomous stage

# 12

Performance improves quite rapidly at this stage. Self-talk diminishes considerably, and anticipation and consistency continue to improve. The ability of learners to detect some of their own errors in performing various skills represents an important development at this stage. Generally, the associative stage lasts longer than the cognitive stage for most individuals.

### **Autonomous Stage**

In the **autonomous (application) stage**, movements become almost automatic and very proficient. Attention demands are dramatically reduced, providing an opportunity to focus on other aspects of performance, such as creativity and strategy. The ability to analyze environmental stimuli is enhanced during this advanced stage, and relevant cues are quickly detected with increased accuracy.

At the peak of their careers, professional hockey players are clearly operating in the autonomous stage. Their hockey skills are so well developed from years of practice and experience that they are able to concentrate on creative plays on the ice that often seem impossible to the average player.

It is equally remarkable to see a refined pianist play with speed and fluidity, but also with creative or imaginative flair. Such performances are the result of a great deal of practice and dedication. Performance improvements during this stage, however, are relatively slow because the learner has already reached such a high level of proficiency before the stage begins. This is not to say that learning stops here, because other less obvious gains (such as a reduction in anxiety and mental effort required for skill execution and an improvement in techniques) may result.

### **Coaching Basketball in Stages**

Knowing the stages of learning a skill and the changes that occur as motor learning takes place is critical for coaches and instructors. Using a sport that most students are familiar with (like basketball) can help them understand the important features of the learning stages (see TGS 12.2). Discussion Guiding Ouestion

LESSON 1

What are the key features of the autonomous learning stage?

Autonomous or application stage: movements are automatic and very proficient; attention demands toward movement details are dramatically reduced; attention is directed toward other aspects of behavior (e.g., creativity); performance improvements are relatively slow and less obvious (e.g., reduction in anxiety levels)

# **The Importance of Feedback**

Highlight the importance of feedback in coaching and teaching skills. Discuss the various types of feedback instructors can use, and differentiate between knowledge of results and knowledge of performance. Students can complete student workbook activity **12.2.2** on page 144 to evaluate their comprehension of the topic.

# Motor Learning in Practice

12 <sup>d</sup>

# Feedback for Skill Learning

Then we practice motor skills we are continually receiving information that is related to our movements, both during the performance and as a result of it. This information constitutes feedback in the true sense, which plays a strong role in motivating, reinforcing, and shaping behavior in a skill-learning environment. Feedback informs the learner about significant strengths or weaknesses that may have been detected during a performance. Without it, practice and, in turn, learning and performance become far less effective.

There are various types of feedback, and the following sections will highlight some of the strategies instructors may use when providing feedback to learners. Feedback is either intrinsic or extrinsic and can be further subdivided into knowledge of results and knowledge of performance (Figure 12.1).

Figure 12.1 Feedback is either intrinsic or extrinsic and each type can be further subdivided into knowledge of results and knowledge of performance.

# Intrinsic Feedback

Information that is provided as a natural consequence of performing an action is considered intrinsic feedback. For example, when you throw a dart, you can feel your arm extend, you can see the dart fly through the air, and you can hear it make contact with the board as it hits the bull's-eye. These are all examples of intrinsic feedback.

258 Foundations of Kinesiology

### Motor Learning in Practice 12

When you are practicing free-throw shooting, the success (or failure) of your shots provides intrinsic feedback. More specifically, this is an example of **knowledge of results (KR)** feedback. Other examples of this type of feedback include seeing the dart hit the bull's-eye, watching the tennis ball land in the opponent's court, or covering an excellent distance in a 12-minute walk/ run test.

#### Knowledge of Performance

The feel of your arm extension is related to information about your performance and is thus known as knowledge of performance (KP) feedback. This type of feedback involves the use of the senses for obtaining more or less direct information. Examples include the fine finger sensations felt when playing the piano (feeling of touch), or the crowd noise associated with college basketball games (audio sensation), or the pull in your shoulders when you are pulling on the oar as part of a rowing crew. These sensations are related to the muscle sense that athletes experience (see the box *The "Secret" Language of the Muscles*).

Particularly in the second learning stage, many of these movements are relatively easy to detect directly, without the need for verbal instruction from the instructor or coach.

### The "Secret" Language of the Muscles

Seasoned athletes can tell how good their performance was, almost as well as a panel of judges, by instinct alone. "On my first try, I knew it was a good jump as far as rhythm and takeoff. But the second try was even better. I really noticed it." Good long and triple jumpers or even discus or javelin throwers can often tell with great accuracy how far they have jumped or thrown without even looking at the measurements. Experienced athletes "measure" and judge the quality of their movements using stimuli that are naturally present in their bodies during the execution of the movement. That is muscle sense at work.

111

**Muscle Sense** For any activity, hundreds of muscles are normally involved in a highly specialized interplay to gather information about the movement and its execution. This **muscle sense** (or **muscle feeling**) can be thought of as the sum of all the sensations that result from every movement of all the limbs in the body (Table 12.2). Special receptors in the muscles, tendons, and joints (called "spindles" because of their appearance) constantly supply information about the position of each joint (i.e., about fixed body positions and the course of the movements). The stimuli that cause these movements are the result of pressure and tension in the muscles and tendons. Without a well-developed muscle sense, athletes would have difficulty performing at their best, and mastering any movement or even trying to execute movements already learned would be almost impossible without this important source of intrinsic feedback.

Muscle sense is not alone, however, in gathering information about movement sequences. Other sensory organ receptors are stimulated simultaneously with every movement, meaning muscle sense works in close

Studying Human Movement and Health 259

Terminology A!ert

The term *muscle sense* is often used interchangeably with the terms kinesthetic sense and proprioceptive

feedback in motor learning literature.

### **Getting a Feeling for Muscle Sense**

Muscle sense is critical for long-term skill development, but teaching it can be challenging because it is largely based on feeling and may be difficult to verbalize. Students can do a few simple exercises to get them thinking about muscle sense. Ask them to dribble a basketball, focusing on the feeling in the hands and the muscles of the arms. How do these sensations change as they bounce the ball harder or softer against the ground? Students can also think about the feelings they

experience when they hit a tennis ball on the racket's sweet spot, throw a spiral in football, hit a perfect float serve in volleyball, and so on.

### "Intrinsic feedback from the muscles gives athletes a feel for their performances."

Muscle sense gives an indication of the strength, force, speed, duration, direction, and extent of any movement.

- What role does muscle sense play in providing feedback to athletes?
  - Muscle sense is a source of intrinsic feedback that gives an indication of the strength, force, speed, duration, direction, and extent of any movement. The internal stimuli naturally present in the body constantly supply information about the position of each joint to help athletes "feel" their performances.
